

AI & ML COLLABORATION WITH NETWORKING EMBEDDED & WIRELESS SYSTEMS

Abstract

Machine Learning (& deep learning) are branches of Artificial Intelligence consisting of statistical, probabilistic, & optimization techniques (often inspired by nature & its phenomenon) that allow machines (computers) to learn from previous observations recorded by humans. These machine learning algorithms when combined with other technologies especially Computer Vision can be used to perform very intuitive yet difficult human-like tasks, using these algorithms, humans can enable computers to learn about certain things like recognizing an object in an image, classifying text into different categories on the basis of its feature(s), etc. Since machine learning can do these difficult tasks easily & without the requirement of manpower, the range of fields in which machine learning can be used is very wide whether it be logistics, agriculture, info technology, healthcare, & many more. Here AI & ML, related to Networking, embedded systems & wireless systems along with their architecture, case studies, algorithms & flowcharts are explained for better understanding.

Keywords: Artificial Intelligence; Machine Learning; Networking; Embedded Systems; Algorithms; Diagnosis; Prognosis; Data collection

I. INTRODUCTION

Artificial intelligence may be a field of consideration that gives computers human-like insights when performing an assignment. When connected to complex IT operations, AI helps with making way better, quicker choices & empowering prepare mechanization. Machine learning can be depicted as the capacity to ceaselessly "measurably learn" from info without unequivocal programming. The benefits of executing AI & ML innovation in systems are getting to be progressively apparent as systems ended up more complex & dispersed which comes about in investigating, enlivening issue determination, & giving remediation guidance. AI & ML can be utilized to reply to issues in real-time, as well as foresee the issues sometime recently they happen. Utilizing AI & ML, network analytics customizes the arranged standard for alarms, diminishing commotion & wrong positives while empowering IT groups to accurately identify issues, patterns, peculiarities, & root causes. AI & ML methods, besides expansive info, are too utilized to decrease questions & move forward the level of choice making.

The AI & ML innovations have major significance for overseeing & observing today's systems in collecting mysterious telemetry info over thousands of systems giving learning that can be connected to person systems & individual security & countermeasures for systems. Each network is one of a kind, but AI methods let us discover where there are comparable issues & occasions & direct remediation & a few ML calculations may entirely centre on a given network.

Network automation in AI & ML can gain insights through analytics & AI & ML that guide more trusted automation processes that lower the cost of network operations & provide users with an optimal connected experience. These technologies help IT automation for the deployment & management of network policies, the integration of zero-trust security solutions to help ensure network consistency & the identification & classification of network devices. As time moves on, AI will have the increasingly qualified network to continue learning, self-optimizing & even foresee & repair service degradations earlier occurred.

AI, Machine thinking & prescient analytics is other critical category of AI. Machine thinking employments obtained info to explore through an arrangement of conceivable choices toward an ideal result. MR is well suited for tackling issues that require profound space ability. MR may be a complement to ML since it can construct the conclusions displayed by ML & analyze conceivable causes & potential advancement alternatives. Prescient analytics alludes to the utilisation of ML to expect occasions of intrigue such as disappointments issues, with the utilisation of a show prepared with chronicled info. Mid- & long-term expectation approaches permit the framework to demonstrate the organisation to decide where & when activities ought to be taken to anticipate arrange rotting from happening.

Here, integrating AI with advanced integration in operations in daily life requires huge data sources that must be transmitted through many high-speed computers in remote server farms. However, neural networks apply many algorithms as an alternative to fulfil the task at hand. Embedded systems process the knowledge required to integrate related hardware & software that can be used to apply AI & machine learning techniques. Artificial intelligence is a great technology & application where current solutions need better

automation or optimization & none of them is good using traditional approaches. So, when people say AI in the network means using AI techniques to support network operations, configuration & management, or play a supporting role. On the other hand, networks with machine learning, deep learning, & other AI techniques are used to manage the network predictably & proactively, & then AI/ML/DL becomes the driving force for operations & management. network or catalyst of network activity. We call this type of network an AI-powered network.

II. APPROACHING THE 5G NETWORK WITH AI & ML

Remote benefit suppliers have conveyed both the 3GPP, LTE & 4G LTE with the targets of expanding crest info rates for downloading & uploading & giving a versatile & versatile framework. However, the client request is expanding broadly, making a bigger sum of organised activity, & challenging the achievability of the existing network. Several ventures have been made within the past few long time to confront this challenge, such as the 5G-TRANSFORMER, a extend centred on the creation of a virtualized layered base which empowers client benefit execution, gathering & joining together the network & transport capacities. In this contention, we'll centre on the AI & ML stage, a modern theme presented in this extent which can run machine learning calculations utilizing info collected by a watching stage, another advancement brought by 5G Growth. We make a point regarding ML to show that's effective in taking a free choice approximately vertical cut instantiation & reuse, making strides in asset utilization.

Potential benefits of introducing AI & ML into communication systems include the following

1. To start, due to the dynamic nature of wireless communication channels, particularly in B5G situations, channel & interference models are exceedingly complex in practice. By learning from communication data & existing knowledge, machine learning algorithms may automatically extract info from unknown channels.
2. Second, there is an urgent need for worldwide optimization of communication resources & fine-tuning of system settings as the density of wireless access points keeps rising. However, these tasks are notoriously challenging to complete using current methods due to the vast amount of resources, system parameters that must be optimized, & their associated correlations.
3. Finally, by identifying behavioural patterns & responding promptly & adaptable to diverse circumstances, such as forecasting traffic & planning rather than merely reacting to unforeseen events, ML will actualize the learning-based adaptive design of networks.
4. Enhanced mobile broadband, ultra-reliable LLC, & mMTC are three main categories of needs that the 5G cellular network has been standardised to answer.
5. The current 5G wireless infrastructure is neither flexible nor intelligent enough to meet these needs effectively. To accommodate service heterogeneity, the coordination of many connections' technologies add on-demand service deployment, and the growth of 5G & 6th Gen wireless demands an architectural shift.

Potentials of AI & ML for 5G communications include:

- 1. Enhanced mobile broadband (eMBB):** Enables new applications with increased data throughput requirements over an even coverage area. Examples include virtual reality & streaming ultra-high-resolution video.
- 2. Massive machine-type communications (MTC):** The scalable connectivity needed for increasing the number of wireless devices with the effective transmission of tiny quantities of data across broad coverage areas is a major feature of 5G communication services. This kind of traffic will be produced by applications like body-area networks, smart homes, IoT, & drone deliveries. MTC must be able to accommodate brand-new, unanticipated usage.
- 3. Ultra-reliable low-latency communications (URLLC):** Mission-critical applications, autonomous driving, V2V communications, high-speed train connectivity, & smart industry applications will prioritize dependability, low latency, & mobility over data rates in connected healthcare, remote surgery, & mission-critical applications.

III. 5G GROWTH ARCHITECTURAL INNOVATIONS

The 5G Growth venture is to develop the usefulness, adjustability, mechanization, recital & safety of the pre-existing stand. Which requires a sequence of designs, algorithms & structural modernizations. Grouping of related architecture is a perpendicular provision which monitors & backs AI & ML in significant circumstances of our effort. It gathers, stockpiles & a piece of course info provided by employed services. These procedures could be advantageous for further data processing components.

AI & ML techniques could be represented around the respective info. It also includes a smoother measured gathering on solid cautions actuated by verticals in short of delay utilizing informing communication capacities between the sub-modules of the observing program. With AI/ML techniques:

ML can be exceptionally valuable as its imperative choices are present in profoundly solid situations in 5G systems.

The theory is arranged as follows:

1. Focuses on the 5G Growth models, the principles based on the model in which it would be employed.
2. A comprehensive understanding of layers is given in this part & also the creations are useful for the work which were provided to the platform.
3. Presents the idea of 'network slice reuse' mechanization, the fundamental of work, & how can it mark the representation of VNFs in the system.
4. The meaning of the algorithm is provided in this part & filtered for implementation.
5. Concentrates on the service occurrence that requests emulators used to generate data suitable for the dataset which will be used to teach the model.
6. Explains ML model, briefing the process of arrangement & choosing the greatest one based on the most precise outcomes.

IV. THE 5G EVOLUTION ARCHITECTURE

5G systems are proposed to operate a long extend dissimilar administrations, individually along with its prerequisites in standings of cessation & materials, ranging from Industry 4.0 to Transportation & Energy. It's vital to construct a modern system that could oversee the before-mentioned must encounter them in a versatile mode. The 5G Growth development offers a framework that provides the connectivity requirements & smoothens the working of new innovative digital use cases. The framework is constructed on the basic platform, 5G transformer, that visualizes the design & creating a scheme that fits the purpose & makes full use of the resources that previously hold important pillars for 5G Network slicing & v MEC.

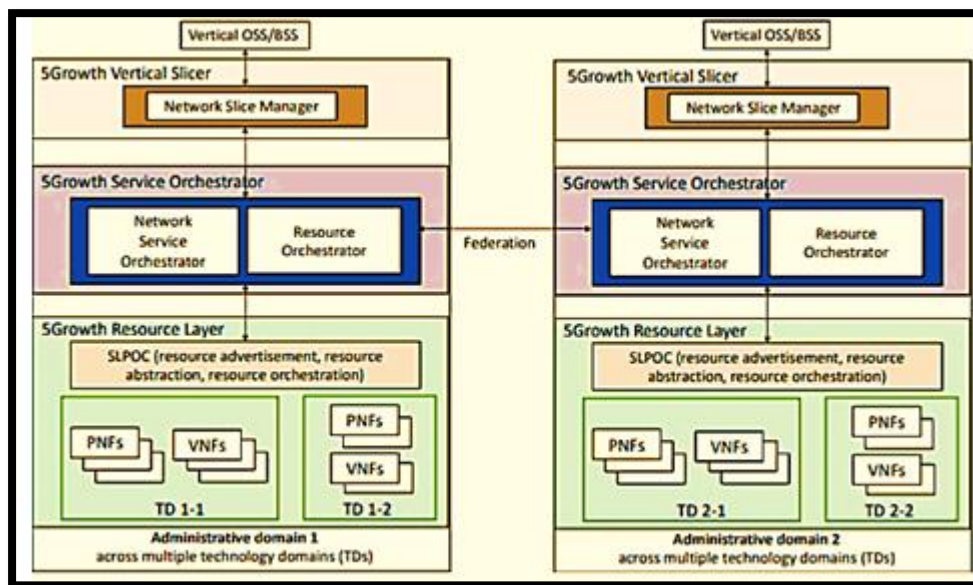

Fig 1: 5G Growth Architecture

The framework is imagined to support multiple integrations of contributors. To succeed for this reason, via the new regularized set of APIs, the system hides the difficulties from the verticals, which are allowed to assign their resources & the required SLAs.

The system comprises three different factors:

1. 5Gr-VS, received from 5GTVS, the access opinion designed for provision requests from the verticals, which manages their connection of services to slices & network slice administration.
2. 5Gr-SO, received is responsible to maintain the balance of services across various territories, & organizing resources to pass to the 5GT-VS.
3. 5Gr-RL, received from 5G-MTP, provides a physical & virtual network property for service employment & network slice execution.

It manages the distribution of resources that can be provided by other managing domains while concealing it from the vertical domain that enters the system via a single NFVO-NSO & the resource orchestrator are the two primary components of this layer.

The MTP is made in the following way:

1. **Abstraction engine:** It generates a mental representation of the resources that are available to the Service Orchestrator;
2. **Database:** This contains data about domain resources. It can be updated by an external SQL server that handles all the worries
3. **Dispatcher:** it regulates how the 5GT-MTP components interact with one another;
4. **Local placement algorithm:** it handles VNF configuration, choosing the precise positioning, & obtaining the best resource utilization;
5. **Monitoring driver:** It coordinates communications between the Monitoring platform & the MTP while creating performance-controlling tasks.

V. AI/ML INTEGRATION WITH 5G NETWORKS

It has opened the entryways to a huge number of distinctive utilize cases with their different needs in terms of assets & inertia. It is subsequently conceded how critical is the computerization of arranging & benefit control. This drives the presentation of modern traits within the 3GPP articulations as the Network Info Investigation. This work will empower the collection & survey of data inside concurred capacities & Open Radio Get to organize radio-related arrangements & move forward execution through AI/ML. The 5G Development Extension focuses on building a 5G AI & ML foundation to realize such computerization, for preparing, storing & deploying AI/ML models within the 5Growth foundation implemented in the 5G transformer system. Integration is made possible by creating a centralized & precise environment. Two frameworks communicate in conjunction with the base: the 5Growth Vertical-Oriented Checking Framework & a common framework requiring a prepared demonstration. The 5Gr-VoMS gives crude info to the 5Gr-AIML stage which collects them as preparing info to be utilized to prepare different models. The 5Gr-entity communicates with the stage through the Interface Supervisor to ask for new prepared AI/ML models. The workflow is as follows:

Planning data is gotten from the 5Gr-VoMS & depicted to make a planning dataset saved inside the HDFS Dataset Capacity; A 5Gr-entity asks the 5Gr-AIMLP for a demonstration had to satisfy the exact prerequisites to ensure a rectify benefit prepare or to respond to a few identified vacillations. In case the demonstration has never been prepared, its viability has become void or starting preparing should be given, a preparing work is sent to the computing bunch, or it is specifically brought from the Model Storage. The Hadoop cluster performs a preparing job using the right piece on the precise dataset present within the Dataset Capacity. Once the preparation is completed, the Demonstrate Capacity & the prepared demonstration are recouped from the Demonstrate Capacity & returned to the asking. 5 Gr-entity which can utilize the show to finalize the at-first asked expansion.

VI. ML-DRIVEN NETWORK SLICE REUSE

The execution of an AI/ML-powered program in the framework brings various upper hands in the 5G growth system. This alteration can clarify the improvement of calculations to be more secure & more grounded than standard ones. AI-based calculations adjust superior to the dynamic conduct of organised cuts & respond in real-time to startling events.

Our work is centred on the robotization of arranged cut representation, done by the authority interior the Vertical Slicer. Within the light of info, it chooses whether an unused virtual machine must be spoken to for that VNF or in case an existing case of the same VNF may be utilized to serve the modern approaching request.

The workflow is given by:

1. Dataset built via info since the monitoring platform & VSD catalogue.
2. ML archetypal is fitted & the training building is created in the initial phase.
3. ML archetypal is verified with the preferred technique k-fold cross & evaluated;
4. Arbitrator asks the qualified archetypal of AI & ML stand for VNFs initialization.
5. Vertical service appeals to reach VS front-end;
6. After being refined by the VSI/NSI Coordinator, the appeal is passed to the Arbitrator to decide how to express the service & its VNFs;
7. The Arbitrator asks the no of occurrences from the initial database to give the accomplished model for conclusion;
8. Trained model forecasts the best discontinuation class arrangement & returns it to the Arbitrator
9. Consequences are returned to the VSI/NSI Coordinator. The VSI/NSI Coordinator continues the service representation process & communicates with the Service Orchestrator.

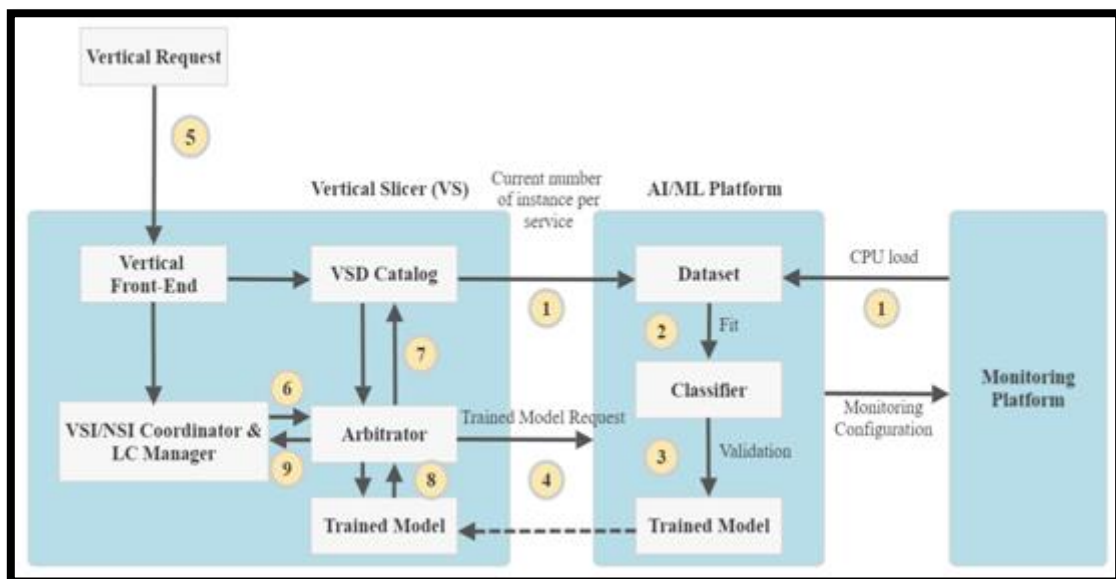

Fig 2: The Workflow of 5G Model

VII. MACHINE LEARNING APPROACH

After the dataset is made an ML model which can be able to classify each setting to the finest canister course of action. The problem can be a directed learning problem, where the machine learning duty of the machine is to learn a job that leads to an estimate of the input value to a particular label based on a set of labelled preparatory info.

The induced work can be utilized to outline unused reasonable inputs to the right label.

1. Find the class of training samples.
2. A set of input objects & parallel names are collected agreeing to estimations & tests.
3. Discover the commonplace input characteristics of the learned work. The input is regularly modified in a characteristic vector, comprising of the vital restrain which clarifies the conditions. It is vital to watch the number of highlights considered to maintain a strategic distance from the revile of measurements.
4. Discover the structure of the learning capacities & the comparing calculation. This is often the portion of the method which can be clarified & encourage underneath.
5. Modify the show. A few calculations require a certain measurement combination to reach the most excellent precision. They can be assessed using cross-validation utilizing diverse sorts of parameter looks.
6. Check the exactness of the work. After modification & learning, the work done is evaluated by deciding to run on a test set different from the preparation. Supervised learning involves different tasks depending on the type of income from work. Consider it a fallback if the yield is quantitative & a classification task if the yield is quantitative. Below, we'll focus on the various ML computations used to create the model.

Flowchart Regarding Classifier Model

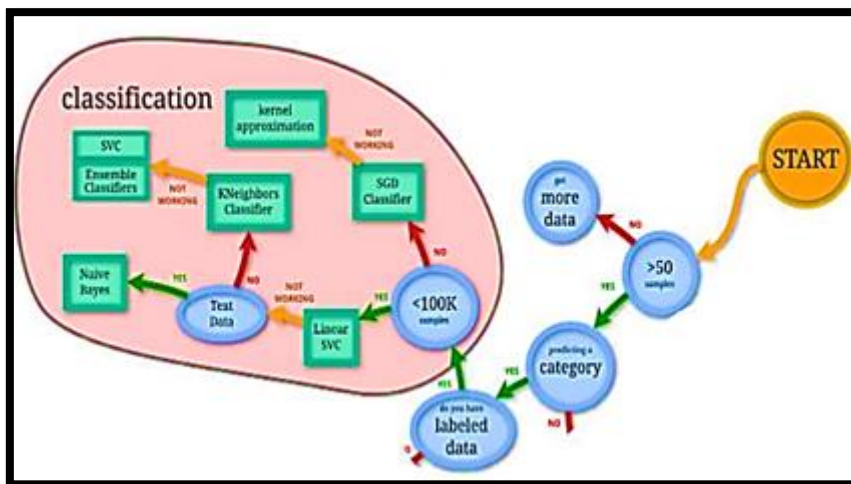

Fig 3: Classifier Model Flowchart

1. **Nearest neighbour classifier:** The observations in the training set that is closest to x in the input space are used by nearest-neighbour techniques to create Y . The following definition applies to the k -nearest neighbour fit for Y :

$$\hat{y}(x) = \frac{1}{k} \sum_{x_i \in N_k(x)} y_i$$

Here, $N_k(x)$ denotes the area around x that is determined by the k nearby training sample points, x_i . Based on what it has learnt from the dataset, the classifier built using this equation compares fresh test data with training data to determine which label is right. It is a memory-based bivariate method. The whole dataset's storage, which may be fairly expensive to do if it's a big dataset, is one of its key aspects. It makes fewer assumptions than constant models, which generalize training data, on the other hand.

Using the label that is most prevalent among the k neighbours, we may categorize an inquiry point x_0 by locating the k training points $x(r)$, $r = 1 \dots k$ closest in proximity to x_0 . Although it is fairly straightforward, k -nearest-neighbours is employed in a variety of classification situations, & it works well when each class has a large number of exemplars & the decision limit is very erratic.

- 2. Tree classifiers:** Tree classifiers work by partitioning the feature space into several rectangles & placing a straightforward model within each one. We first describe one of the standard approaches, use it to solve a regression problem, & then use it to solve our categorization. In obstructing a tree, we concentrate on recursive binary partitions, which divide the space into two areas & shape the response according to the mean of Y in each zone. To greatest fit, the optimal split point for a variable is selected. The split repeats & comes to an end when a stop condition is satisfied.

The size of the tree is one of the modifying parameters for tree classifiers. Different strategies can be used to control it, such as stopping the division when the sum of squares drops as a result of the split above a certain threshold. This, however, is not the ideal option because it can reduce the likelihood of selecting an unnecessary split that results in a superior one. Growing a big tree & then cutting it with cost-complexity is the answer to this problem.

In an intersection m , representing a region R_m with N_m observation, let the percentage of observations in the intersection from class k (m). The formula for the majority class in node m is $k(m) = \text{argmax}$. Each node's impurity is an identifier to specify a criterion for the tree's growth conclusion. It may be calculated in a variety of methods, including using the cross-entropy or the Gini index, which are better suitable for numerical optimization because of their differentiability. Additionally, they are more sensitive in node n

$$\hat{Y}(x) = \frac{1}{N_m} \sum_{x_i \in R_m} I(y_i = k)$$

- 3. Support vector classifier:** Support The foundation of vector classifiers is a technique for improving the hyperplane that best divides data into various classes. Taking the training set's N pairs of data With $x_i \in R_p$ & $(x_1, y_1), (x_2, y_2), \dots, (x_N, y_N)$ We define a hyperplane as follows using the formula: $CST + 0 = x:f(x) = 0$

Where β is a unit vector

$\|\beta\| = 1$. The classification rule applied by $f(x)$ is $G(x) = \text{sign} [x'\beta + \beta_0]$ the issue

with Optimization $\beta_0, \beta_1 \dots \dots \beta_p, \epsilon_0, \dots \epsilon_n$ maximize M subject to $\sum_{j=1}^P \beta_j^2 = 1$

The constraint d is as follows: $y_i(x_i^T \beta + \beta_0) \geq M(1-\xi_i)$

which calculated the overlap in the relative distance, thus producing a convex problem. The formula can be rearranged to discuss it with Lagrange multipliers. The equivalent form i

$$\beta_0, \beta_1 \min \frac{1}{2} \|\beta\|^2 + C \sum_{i=1}^N \xi_i \geq 0, y_i(x_i^T \beta + \beta_0) \geq 1 - \xi_i \forall i$$

The classifier's modifying parameter in this case is the cost parameter "C." In terms of, 0 & I, the Lagrange main function is minimized. By setting the derivatives to zero, we obtain

$$\begin{aligned} \beta &= \sum_{i=1}^N \alpha_i y_i x_i \\ 0 &= \sum_{i=1}^N \alpha_i y_i \\ \alpha_i &= C - \mu_i, \forall i \end{aligned}$$

Summation which dual function by substituting these values into the equation. $L_D = \sum_{i=1}^N \alpha_i - \frac{1}{2} \sum_{i=1}^N \sum_{i'=1}^N \alpha_i \alpha_{i'} y_i y_{i'} x_i^T x_{i'}$ which establishes a limit on the objective function whose goal is maximization, subject to $0 \leq \alpha_i \leq C$ and

$$\text{the } \sum_{i=1}^N \alpha_i y_i = 0$$

The solution for β has the form

$$\hat{\beta} = \sum_{i=1}^N \hat{\alpha}_i y_i x_i$$

Matching the dataset We noticed that the final dataset had an unbalanced representation of the classes. Certain machine learning algorithms may become biased as a result & may entirely disregard the minority class. We can prevent this by randomly rearranging the learned dataset using two basic methods:

- **Random oversampling:** samples from the minority class are duplicated at random, which might cause certain models to overfit.
- **Random under-sampling:** remove samples at random from the majority class, which may result in the loss of data critical to some models.

We employ these two resampling techniques using the Python variance-learn module. We'll pick the approach that produces the most accurate predictions.

Since no assumptions are made regarding the data, these techniques are referred to as "naive resampling," which is necessary for huge datasets. They may be applied to multi-class classification as well as binary classification, but their main usage is to just apply to the training dataset to influence how well the models fit.

The final result is subsequently shown to the user & is comprised of the performance metrics acquired in each loop. Although computationally costly, it does not waste data.

Restrictions of Machine learning for 5th Gen networks:

- **Data:** The kind of data is a key consideration when determining which sort of learning to utilize, as superior data is necessary for Machine Learning apps. The quality of ML depends on the data it is fed.
- **No free lunch theorem:** According to this theorem, if all potential data-generated distributions are averaged, every ML algorithm will perform equally well when attempting to infer unseen data. As a result, the objective of ML is to identify what type of distribution is important to a given 5G application & which ML algorithm has the greatest presentation of specific facts, rather than to try to find for the greatest learning algorithm possible.
- **Hyperparameters selection:** In ML algorithms, hyperparameters are parameters that are established before training. As they affect the parameters which are efficient from the knowledge results, these values need to be carefully chosen.
- **Interpretability vs accuracy:** The complicated interplay between independent factors can be challenging for stakeholders to comprehend & may not always be profitable. As a result, there must be a trade-off between fully accurate analysis & data interpretation.
- **Privacy & security:** The alteration of an input sample to make a different sort from its true class is one example of a combative outbreak that might be made on machine learning algorithms.

VIII. AI IN 6TH GEN NETWORKING

1. The 5th Gen Network is best known for clouding networks with architectures based on micro services, next-generation or 6th Gen-era networks are associated with intelligent network orchestration & management. However, the alliance between 6th Gen & AI can also be a double-edged sword in many cases, because of AI's applicability to protect or violate security & privacy. In particular, the end-to-end automation of future networks requires proactive threat detection, application of intelligent mitigation techniques, & ensuring the realization of autonomous 6th Gen networks. Thus, consolidating & reinforcing the role of AI in 6th Gen network security Artificial Intelligence & 6th Gen Confidentiality: Prospects & Encounters
2. Advanced change is anticipated with 5G systems that have as of now started & proceed to advance over this period, the 6th Gen statement period envisions how people will be connected with the computerized virtual universes past 2030. The forthcoming system should have innovative innovations which empower the computerized simulated universes that associated insights, to address the communication & organizing challenges past 2030. Whereas ordinary applications such as mixed media spilling will stay, writing

envisions modern application spaces for 6th Gen frameworks such as multisensory XR applications, CRAS, & remote BCI. Holographic telepresence & eHealth counting in-body systems are many other 6th Gen utilize cases that request greatly tall info rates, low idleness & ultra-reliability. The advancement of 6th Gen applications spaces demands an imaginative organize engineering past current organize plans. An open & dispersed reference system for 6th Gen engineering building squares characterized by 'Nokia Bell Labs' includes 4 major interworking components. These are stage, useful, dedicated, & coordination, layering up the physical layer to the benefit layer taking after recognizing highlights

3. **The confidentiality threat landscape of 6th gen pre-6th gen confidentiality:** Arrange softwarization innovations in 5G such as SDN, NFV, MEC, & arrange to cut are still pertinent for 6th Gen frameworks; in this way, their confidentiality issues would stay in 6th Gen. 6th Gen envisions the realization of the 'IoE', a group of varied gadgets. Elemental gadget confidentiality model trusting on SIM cards isn't a viable sending for you in 6th Gen, particularly with the little frame calculate gadgets such as in-body sensors. Key dissemination & administration capacities are profoundly wasteful in such an enormous organisation. The resource-constrained IoT gadgets cannot manage complicated cryptography to preserve solid secrecy, making them an essential target of assailants. These gadgets can be compromised & possibly utilized to start assaults. Info collection by hyper-connected IoE to serve 6th Gen applications raises protection issues. Info burglary by misusing resource-constrained IoT gadgets will influence info protection, area protection, & character security Confidentiality of 6th Gen Architecture: 6th Gen compartments will shrink from little cells to "tiny cells", & a denser arrangement of cells, work systems, 'multi-connectivity', & 'D2D communications' will be a standard. Malevolent gatherings have distant better; much better; a higher; a stronger; an improved stronger potential to assault a disseminated organize with more helpless gadgets, each having a work network, subsequently expanding the threat surface. The definition of sub-networks requires an alteration within the privacy technique. Privacy arrangement for the enormous number of gadgets inside each sub-network by the wide zone organised is distant from down to earth. Various levelled confidentiality component that recognizes the sub-network level communication secrecy & sub-network to wide zone organize secrecy would be distant better; a much better; a higher; a stronger; an improved a higher approach in 6th Gen. The 'RAN-Core' merging kinds higher layer RAN capacities more centralized & coexists with the disseminated centre capacities as UPMS & CPMS, conceivably at the edge. Aggressors can aim 'UPMS & CPMS', influencing numerous transistor units aided by micro-services. 6th Gen systems will coexist with systems like ZSM engineering to empower brief time-to-market of administrations, moo working fetched, & decrease human mistake.
4. **Confidentiality of 6th gen technologies:** 6th Gen depends on AI to empower completely independent systems. Hence, assaults on AI frameworks, particularly ML frameworks will influence 6th Gen. Harming assaults, info infusion, info control, rationale debasement, demonstrate avoidance, demonstrate reversal, demonstrate extraction, & enrolment introduction assaults are potential confidentiality dangers against ML frameworks. The collection of more highlights permits AI frameworks to perform way better. Assaults on collected info & the unintended utilisation of private info, lead to

protection issues as the info handling is as a rule not obvious to the clients. 51% of assaults are attainable with quantum computers to destabilize the blockchain. The present 5th Gen ordinary doesn't concern privacy issues due to quantum computing; or maybe, it depends on conventional cryptography like ECC. The display secrecy instruments are based on key cryptography which is powerless against significant computer-based assaults as the 6th Gen time will stamp the nearness of quantum computers.

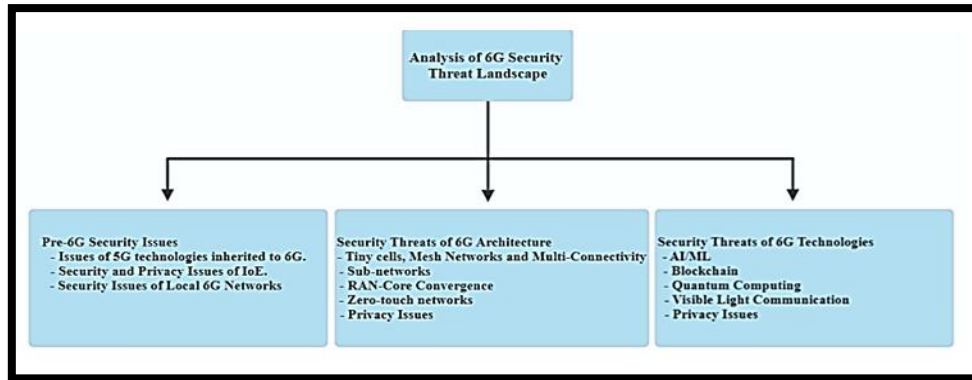

Figure 4: Security Threat Analysis landscape of 6th Gen Networks

IX. ISSUES AND COUNTER-MEASURES

- 1. Confidentiality issues of AI Issues:** 6th Gen accomplishes associated insights using AI-enabled capacities, particularly with ML frameworks that are subjected to secrecy dangers. Harming assaults impact the learning stage of an ML framework, which leads the show to memorize mistakenly

Solutions: Likely countermeasures like antagonistic ML & moving target guard can make strong AI frameworks. Input approval & strong learning against harming assaults, antagonistic preparing & cautious refining against avoidance assaults, & differential security & homomorphic encryption against API-based assaults are other protection components.

- 2. Confidentiality issues of artificial intelligence issues:** Due to AI's capability for large-scale info investigation combined with the speed of future computers & the mechanization next-gen systems, AI can effectively find the middle ground protection. 6th Gen requires a gigantic sum of client info collected through millions of gadgets, & the clients do not predict how outside frameworks handle their info.

Solutions: Unified learning conserves info security by forcing physical control to preserve info closer to the client. Homomorphic encryption, which permits performing numerical operations without decoding info, forces a specialized control for protection conservation

- 3. Ethical issues of AI issues:** Completely mechanized AI-based 6th Gen systems require lesser human mediation in organized operations. The way machines learn varies from how people see things, & machines don't address moral contemplations as people. AI

frameworks carry on agreeing to the way they were instructed & prepared. In any case, they cannot carry on against the rationale in remarkable circumstances as done by people.

Solutions: The “Ethics by Design” approach brings the wrangle about moral suggestions at the essential arrange of the plan of AI frameworks. Considering morals at the early organize may be valuable in brilliantly 6th Gen frameworks. Rules, laws, & directions are possible measures to address info ethics & proprietorship within the setting of the 6th Gen to attain an appropriate adjustment between hazard & advantage. Robotized machine morals ought to be characterized to guarantee info security in future systems.

- 4. Using artificial intelligence for assaultive 6th gen issues:** Capacity to create network-wide cleverly choices are conveyed edge-based design; AI itself could reveal the designs inside a huge capacity of info at distinctive levels. Thus, components have the potential to reveal vulnerabilities of the network

Solutions: The countermeasure for AI-based cleverly assaults are additionally the usage of more cleverly protection frameworks. They are enabled by AI itself utilizing conveyed insights. Strategies could be a proactive degree that presents dynamicity to the arrange, & debilitates of AI-enabled aggressors. Quantum ML seems to be utilized to plan progressed protection procedures to stand up to AI-based attacks

X. NETWORKING MODELS

Black boxes are currently popular by means of Artificial Intelligence models, particularly DL models. Since complex DL models may more accurately estimate functions, resulting in considerable accomplishment in resolving well-known comp visualization issues, the complication has expanded to comprise added limitations.

However, there are numerous real-world challenges to using AI models to address networking issues, including:

- 1. Data discrepancy:** Networking data, in contrast, to picture & text data, have inherent characteristics including time diversity, space diversity, & a large figure of categorical structures. Due to lack of labelled facts & a variety of events, it is therefore challenging to reproduce the success of Artificial Intelligence in networking.
- 2. Feasibility:** Even though most AI-based resolutions currently in use function primarily in the control plane, a new development has pushed the Artificial Intelligence limits to the statistics plane, which is still difficult assuming the data plane's limited resources.
- 3. Robustness:** There are many flaws in present Artificial Intelligence arrangements which could allow invaders to influence the AI keys & negatively affect the grid
- 4. Trust:** Complex AI models typically use a variety of factors & nonlinear transformations to make decisions that are difficult for humans to comprehend & rely on. This latter aspect is particularly crucial in networks, where operators must comprehend the effects of a choice. Increasing confidence in AI-rel resolutions can help achieve the definitive objective of ethical AI

XI. FREQUENTLY USED AI MODELS

AI models can be classified into two broad categories based on their internal workings & interpretation overhead: “Transparent AI models” & “Opaque AI models”. Commonly adopted models include ‘naive Bayes, random forest, support vector machine, decision tree, & deep neural network’.

Transparent AI model: They are easy to show to humans through simulation, algorithmic analysis, or breakdown since they are simple by design. Models of AI that are clear as crystal & easily understandable include DT & NB. For instance, DT uses leaves to indicate predictions & a hierarchy of nodes to divide input data. DTs are frequently used in the networking industry to address fault-tolerant & time-sensitive applications. The foundation of NB is the idea that the input features are unrelated to one another. % NB runs quickly & makes comprehensible forecasts, similar to DT. If the "naive" assumption is correct, NB can produce accurate predictions using a small amount of training data. Both models provide ways to comprehend how they make decisions.

Opaque AI models: AI models are considered opaque if their predictions are difficult to share. Typical opaque models include RF, SVM, & NN. RF is an ensemble learning technique that enhances accuracy by combining the predictions of various DTs. SVM uses hyperplanes to classify input data by mapping it in a multidimensional space. The structure of organic neurons in human brains serves as an inspiration for DNN design. Advanced ‘DNNs’ could have lots of limitations, & are frequently utilised for a variety of challenging jobs where they have proven to perform exceptionally well.

In comparison to transparent AI models, existing research demonstrates that opaque AI models are more adept at identifying nonlinear patterns & resolving challenging problems. In case of a ‘linear regression model’ is simple to enlighten because the feature input & target output are mapped directly by the linear relationship. But ‘linear regression’ generalizes the situation & frequently fails to address challenging practical issues. In a similar vein, humans may easily imitate the inference of a DT. However, DTs exhibit overfitting & are difficult to generalize. The number of resources needed is another noteworthy distinction among ‘Transparent & Opaque AI models’. The opaque models, whose gauge could turn out to be unmanageably huge, transparent models are significantly simpler & need fewer processes.

XII. XAI TECHNIQUES FOR NETWORKING

1. XAI for results in networking: Different criteria are used to categorise XAI techniques. ‘XAI methods’ could also be globally or locally dependent on the interpretation scope. While local approaches offer interpretations on particular prediction instances, global methods aim for overall model interpretation. XAI approaches can be model-dependent or model-agnostic depending on how heavily they rely on certain AI models. While model-agnostic approaches can theoretically be applied to any AI model, model-dependent methods are specifically designed for a given model. We categorise current XAI research in networking in this area according to interpretation methodologies, such as visualisation, generalization, & feature significance analysis.

- XAI for performance enhancement:** XAI methods ought to generate interpretations that are added intricate to promote performance enhancement. In the end, human specialists must evaluate & extrapolate the functions among input characteristics & output predictions, that are currently solely retrieved by XAI algorithms. Advanced findings & simple recommendations to improve autonomous performance at the model & system level should be generated by XAI algorithms. In particular, XAI approaches should be open about the actions they take to increase the accuracy of model-level predictions. At the system level, XAI methodologies must identify the best traffic types, & network environments, & model service strategies for solutions based on the AI used. Among the performance parameters that XAI should periodically trade off are accuracy, latency, & energy use. Real-time network dynamics, for example, may be used to divide a DNN for cooperative training & inference. Additionally, by including several side branches with various degrees of precision, its responsiveness may be improved (e.g., early exit). Therefore, to effectively extract insights

XIII. DIFFERENT METHODOLOGY FOR XAI

- Feature relevance-oriented XAI:** To evaluate each feature's influence on the choice, feature relevance analysis techniques produce a feature relevance score. to analyse & emphasise the important factors that result in specific forecasts. Using a sample setup, local feature analysis for the UAV-based wireless networks recommended a DRL approach for the best service provisioning. The interpretability of a 5G network latency prediction methodology called XGBoost. The researchers evaluated several conventional XAI techniques & recommended SHAP since it offered the most accurate interpretation. Despite some success in interpreting AI-based solutions, XAI is still a relatively new technology in the networking sector.
- Visualization-oriented XAI:** The upfront for XAI methodology are explained over visualisation that employs dimensionality reduction methods & visual enhancement to produce precise artworks of how an Artificial Intelligence model interacts with its internal components & runs. a platform for monitoring the inference procedure of a convolutional neural network-based network traffic classification engine of commercial quality. The display place may produce a series of grids to show classification procedure & emphasise of crucial components. By interacting with the graphs, human users may therefore have an improved grasp of CNN's categorization procedure.

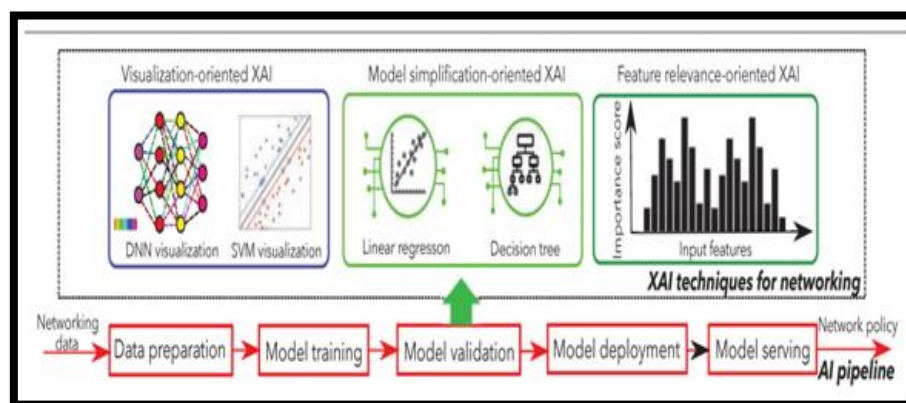

Figure 5: AI Pipeline for XAI Techniques for Networking

XIV. CHALLENGES AND PROSPECTS FOR THE FUTURE

End-to-end network automation is essential as 5G & 6th Gen standards emerge. XAI, which is regarded as a key building block, will enable the next-gen networks to be 'self-managing, self-healing, & self-optimizing'. Yet, there are several challenges that XAI must first get beyond to fully realise its promise for automated network administration. In this part, the five main XAI perspectives—network-specific interpretation, performance enhancement, model amplification, resilience, & trust-building are described.

AI and ML Algorithms related to networking systems, embedded wireless system

1. **A quick method of identifying community structure in networks:** Our algorithm is built on the idea of modularity. The GN community structure method always constructs some split of the vertices into communities for every given network, regardless of whether the network naturally exists in such a division. To determine if a particular division is meaningful, we define a quality function or "modularity" Q as follows. Let e_{ij} be the proportion of the network's edges connecting over services to group j 's $a_i = \sum_j e_{ij}$. Then $Q = \sum_i (e_{ii} - a_i^2)$ is the proportion of edges that are in the biome, minus the value of the same quantity that would be predicted if the edges fell randomly regardless of the biome's structure. $Q = 0$ is obtained if a particular division does not produce more internal plus edges than would have been predicted by chance. Values above about 0.3 seem to indicate a strong community structure. A value less than 0 indicates a deviation from the chance.

This now suggests a new method for determining community organization, though. If a high value of Q suggests a good community division, why not just optimize Q 's overall potential divisions to discover the best one? As a result, we can quickly go past the iterative elimination of edges. Real Q optimization is prohibitively expensive, which is the problem. The number of distinct community divisions is determined sup superscript fend capend $S_n^{(g)}$, which counts the methods to divide n vertices into g non-empty superscript forthe $\sum_{g=1}^n S_n^{(g)}$. Since $S_n^{(1)} + S_n^{(2)} = 2^{n-1}$ for every $n > 1$

Even if the closed form of this total is unknown, it must increase at least exponentially as n increases. It would therefore be necessary to thoroughly search through all potential divisions to find the ideal value of Q , which would take at least an exponential amount of time & be nearly impossible for systems with more than twenty or thirty vertices. Numerous approximation optimization approaches are available, such as simulated annealing & genetic algorithms. Here, we discuss an approach based on a conventional "greedy" optimization technique that appears to be successful. Our approach falls within the larger category of agglomerative hierarchical clustering methods. Starting from the condition that each vertex is a unique member of one of the n communities, we continuously connect the communities in pairs, choosing the join that causes the largest increase (or least decrease) in Q at each stage. An illustration of the algorithm's evolution is a "dendrogram", a tree showing the order of joins. Slicing through this dendrogram at different levels causes the network to split into more or fewer communities and, as with the GN algorithm, we can choose the best slice by finding the highest value of Q Since

the union of two communities with no edges can never raise Q , think only of pairs between which there are edges. These pairs will usually have at maximum m edges, wherein m is the entire quantity of edges within side the graph. The formula for the change in Q that results from uniting two communities is $= e_{ij} + e_{ij} - 2a_i a_i = 2(e_{ij} - a_i)$, which is buildable in constant time. Adding the rows & columns corresponding to the merged captives' up dais a part of the complement e_{ij} in worst-case time $O(n)$ of subscript subscribers result, the algorithm's worst-case time for each step is $O(m+n)$. The approach takes $O((m+n)n)$ time, or $O(n^2)$ on a sparse graph, & only requires a maximum of $n-1$ join operations to generate the entire dendrogram. Finding the ideal community structure is extremely straightforward thanks to the algorithm's additional benefit of computing Q 's value as it runs.

Importantly, by making the initial values of the components of the e_{ij} matrix equal to these magnitudes instead of just zero or one, our approach can be significantly suited to the weighted network where each edge has a numerical magnitude associated with it. Same algorithm as above & take the same time to complete. However, not all networks studied in this study are weighted. Importantly, our algorithm can be generalized to weighted networks where each edge is associated with a numerical force by setting the initial values of the matrix elements. e_{ij} Equals those forces, not zero or one; otherwise, the algorithm is the same as above & takes the same time to complete.

- 2. Deep learning algorithm:** Deep learning is a novel approach to machine learning that aims to build a neural network that replicates the human brain's analytical process for figures, pictures, sounds, & texts. A hidden multilayer perceptron is a component of the learning structure. The input layer, hidden layer, & output layer are the three main layers that make up the deep learning structure, which is modelled after the human brain's hierarchical organization. High-level features are built at each layer by remembering low-level characteristics. The nodes of nearby layers are connected through links, while those of non-adjacent layers are not connected. Each layer's structure may be thought of as a logical regression model.

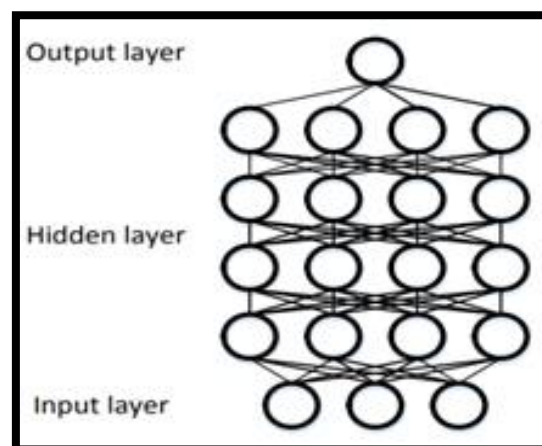

Figure 6: DL Model Hidden

The restricted Boltzmann machine is a synthetic random artificial neural network used in deep learning modelling. It became popular after Geoffrey Hinton & others developed fast learning algorithms for it in the mid-2000s. Visible layer & hidden layer are the two basic components of RBM. The units in one layer are independent of & not linked to those in the other layer. that is,

$$p(h|v) = p(h_1|v_1) \dots \dots p(h_n|v_n)$$

But the weight W connects the two layers. One way to think about the RBM is as a feature extractor. Let vector $\{v_1, v_2, \dots, v_n\}$ & $h = \{h_1, h_2, \dots, h_n\}$ denote the visible units & hidden units, respectively where v_i is the i -th state, & j th the state of the hidden then the energy of the RBM system

$$\text{is: } - \sum_{i=1}^n a_i v_i - \sum_{i=1}^m b_j h_j \sum_{i=1}^n \sum_{j=1}^m v_i w_{ij} h_j = E(v, h|\theta)$$

Where the parameter of the z is $\theta = \{W_{ij}, a_i, b_j\}$ W_{ij} is the link weight between the i -th unit in the higher layer & the j th unit in the current layer; & a_i is the bias of the i -th unit in the visible layer. The buried j 's unit bias is represented by the symbol b_j . The symbol distribution probability (v, h) may be derived below using the energy model after

these parameters have been determined $\frac{e^{-E(v, h|\theta)}}{z(\theta)} = P(v, h|\theta), z(\theta) = \sum_{v, h} e^{-E(v, h|\theta)}$

Where $Z(\theta)$ is the normalized factor. Then, find the marginal distribution of joint distribution of $v: (v|\theta) = \frac{1}{z(\theta)} \sum_h e^{-E(v, h|\theta)}$ Calculating the marginal distribution requires determining the amount of the normalization factor $Z(\theta)$. In reality, it requires $2n+m$ computations to arrive at $Z(\theta)$. As a result, even if the size is acquired by training, the distribution of P cannot be known.

For simplicity, assume that the units of the visible & hidden layers are 0 or 1. The units of the hidden layer are independent given the visible layers, so the activation probability of the j -th is represented. According to the following formula: $P(h_j = 1|V, \theta) = \sigma(b_j + \sum_i v_i W_{ij})$ When the activation function is $\sigma(x)$. The units in the visible layer are similarly independent of one another when the hidden layer is known; hence, the activation probability of the i -th unit is as follows $P(v_i = 1, h|\theta) = \sigma(a_i + \sum_j W_{ij} h_j)$ the simplest method for implementing deep learning is the automated encoder. The automated encoder modifies the settings of each layer based on the characteristics of the artificial neural network in an uncontrolled learning technique so that the output value is identical to the input value. Each intermediate layer essentially represents input data in this manner. Additionally, the automated encoder may replicate the neural network of the input signals, reduce dimensionality, & compress data. Both the RBM & feed forward neural networks are capable of realizing it.

- SVM algorithm:** One of the most widely used embedded level ML algorithms is SVM. SVM is a supervised learning algorithm that can be used for both classification

& regression problems. The algorithm distinguishes between two or more data classes by determining an optimal hyperplane. It separates all classes. Support vectors are the closest data to the hyperplane. If removed, it would lead to a redefinition of the hyperplane itself. For these reasons, they are considered an important part of the data set. The commonly used AI loss function in algorithms is hinge loss. The optimization function is the descending gradient encountered

XV. AI IN EMBEDDED SYSTEMS

AI in an embedded system is a software-based implementation of machine & deep learning at the component level. Which, based on the data gathered & examined, is configured to deliver both predictive & reactive intelligence. In the previous years, a significant change has taken place from cloud-level to device-level processing of AI tasks, data & results. By tradition, complex AI computations, such as constructing search engine results, were accomplished in the cloud data centre. Embedded AI devices have the capability to course the path at the device level for AI models which supports to completion of a suitable task using the obtained results. While the uses & application of embedded AI are massive, here are a few shortlisted commerce where this tech is automating progressions & providing cutting-edge analytics & business insights, & improving customer service, among numerous other benefits.

1. Aviation
2. Healthcare
3. Manufacturing
4. Shipping

Embedded AI methods for embedded industrial applications: AI & ML procedures are plaguing all gadgets & innovations, with cleverly info preparation taken nearer to the implanted frameworks to maintain idleness & security prerequisites. In fact, machine learning is used in the auto sector to create camera systems with excellent features. Utilizing machine learning in industrial computerization. Recently a profoundly important venture appeared important for ML within the space of tall through put flask substantial pieces of machinery. Another completely modern space of ML is built near-infrared spectrometry where prepared systems bolster the quick discovery of chemical fixings.

The 4 AITIA use-cases: The four common use cases that might potentially be affected by AITIA are industrial 4.0 management, smart sensing, network interruption detection, & driving assistance. AI & machine learning are used in smart sensing to improve sensor performance. When compared to traditional methods, machine learning provides a more reliable capacity of identifying interruptions for organising interruption location. AI can assist drivers more effectively from various vehicle vantage points. Last but not least, machine learning recommendations improved step management for equipment like sensors & actuators when used in an Industry 4.0 environment.

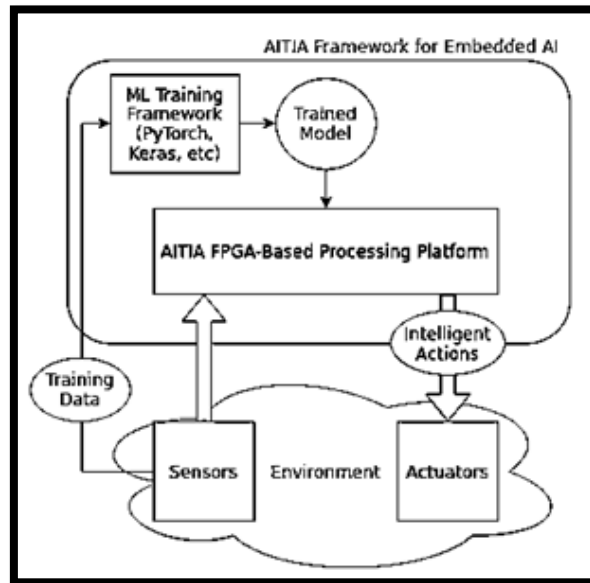

Figure 7: The Working of AITIA

Case 1: smart sensing: The use of near-sensor machine learning contributes to the empowerment of underutilised capabilities for both business & consumers. By bringing insights to the network's edge, the needs for mo idleness & competent transfer speed usage of many applications may be minimised. Additionally, such clever devices may locally process the sensor's data, reducing overall control use, maximising the use of the transmission capacity, & providing safety. A heatmap that overlays the visual & audio data displays the combination of data from the sensors. The following functionalities are highlighted:

1. **QoS improvement:** Whereas low-quality cameras do produce images with usually high resolutions, high acoustic image resolutions hurt overall frame rates because to their high computing demands. By utilising inaccurate profound learning calculations, the quality of acoustic images will be improved in terms of determination as an elective.
2. **Anomaly detection:** The microphone clusters provide extra data that may be used to find irregularities. We will evaluate several ML techniques to abuse this multi-sensory data.
3. **Embedded classification:** Heterogeneous sensor clusters enable the capacity to notice situations in which something else would not be identified by using single sensors by providing multi-sensory data. To prepare this multi-sensory data for the localization & recognition of acoustic events in urban settings, existing ML algorithms will be evaluated.

Challenges: Deep learning algorithms are excellent options for image upscaling, much like the ones attached to infrared & vision cameras. In any case, as named info is necessary for the ML preparation, the requirement for datasets containing acoustic images necessitates additional effort. There aren't enough datasets for the preparation arrangement, even though several arrangements have been presented for peculiarity discovery. To Tour datasets using real recordings, we will abuse our sensor cluster. This will allow us to spot unethical behaviour like completely disappointing receivers, non-linearly weakened mouthpieces, & other abnormalities.

Case 2: Network invasion detection: IDS points to identify interruptions or assaults against computer frameworks. Two different sorts exist NIDS which distinguishes interruptions in a computer network, &HIDS which distinguishes interruptions on a particular host. For such frameworks, we point to explore if the utilisation of ML seems to use their execution. Right now, NIDS usage is rule-based. These rule-based approaches were ensured to ensure against assaults that are unequivocally depicted within the rules, which takes off the arrange vulnerable to obscure attacks. Here, ML may be able to secure by consequently learning regarding unused assaults, rather than as it was depending on a particular regulation.

Challenges: Discovering a network disruption is no simple task for several reasons. First, two different approaches are used to execute localization, each with its own preferences & limitations. On the one hand, interruptions are distinguished from misuses using info on recent assaults. However, anomaly-based interruption discovery frameworks separate attacks depending on how they deviate from typical behaviour. Furthermore, obtaining useful & agent datasets is challenging. The fact that the statistics are typically dependent on earlier datasets not only means that more recent attacks don't exist, but also that the assaults highlighted in those earlier datasets are out-of-date.

Case 3: Driver assistance: AI has been heavily used in a variety of automotive applications & might be a crucial component of many Advanced Driver-Assistance Systems (ADAS) used in automobiles. Question location & image division are the two main areas of the automotive industry where AI is used. AI can be utilized in numerous spaces in cars. From security applications to including extravagance for travellers, it includes a parcel of applications. A few of the key inspiration focuses for utilizing AI in car utilize cases are given underneath:

Driving assistance: Intelligent devices in cars are used for several security tasks, including emergency braking, blind spot monitoring, & vehicle separation, in addition to their original purpose of helping the driver. By examining a variety of sensors, AI in automobiles may spot dangerous situations & either warn the driver or take over the steering to prevent accidents.

- 1. Cloud services:** Drivers of common automobiles can be seen checking engine lights, low battery warnings, & other alarms for assistance. By examining various sensor data, intelligent devices in automobiles can spot problems in time since they start to affect how the vehicle operates. For automobiles with internal combustion engines, defect location & categorization methodology it might show. For defect finding, the vibration data from a wrench point is used. This tactic, also known as engine problems, was notable for having a 97% victory rate.
- 2. Risk assessment:** A driver's actual previous info may be obtained by AI, which can also assess the driver's potential for risk. Several factors affect a driver's ability, including health problems or insufficient sleep.
- 3. Driver monitoring:** AI can recognise the expansion of the human eye & foretell when a driver is stressed. This might be used as a level of security. On occasion, a driver's ECG may be checked while driving as part of a stress detection strategy. In the event of excessive stress levels, this screening is used to alert drivers, their families, or street customers so they can avoid accidents. Driver signals can also be used to operate the entertainment system.

Challenges: In this use case, accuracy & execution present the most difficulties. Since the majority of ADAS operate in real-time, a mistake might have catastrophic results. Therefore, the algorithms used must be forced to safety-critical accuracy. Additionally, the calculation execution idleness needs to be high enough to avoid missing challenging deadlines in safety-critical situations. The computations used have substantial computational & memory requirements.

Case 4: Industry 4.0: Expanding the utility of next-generation sensors & actuators for industry using AI & ML 4.0. This contemporary set of ingenious tools should support self-calibration, vision maintenance, self-organization, & autonomous control. The potential applications to the industry are listed below. 4.0 space.

- 1. Self-calibration:** Intelligent devices can utilise multidimensional data from surrounding sensors & actuators to prepare themselves for usage.
- 2. Predictive maintenance:** Predictive technology may automatically identify mechanical form anomalies & foresee sensor & actuator failures. This info is created collectively from the multidimensional data gathered by the mechanical sensor network, & the breakdown mechanism may be identified.
- 3. Self-organization:** Intelligent devices are connected to a work organisation & are capable of organising themselves significantly to prepare the data for the task at h&& to react if individual nodes fail. As an example, a system of sensors is used to measure temperature at various stages of a mechanical preparation; if one of the nodes fails, the system automatically reorganises & uses previously acquired knowledge to predict the temperature for the failed node.
- 4. Autonomous control:** Intelligent machines might spontaneously optimise mechanical operations while maintaining the required quality criteria & necessitating the least amount of human intervention.

Challenges: High execution security & high consistency are the two main issues. For the formed arrangements to have a minor impact on the generating throughput, there should be minimal activity in gathering sensor data & evaluating actuator communications inputs. Because of this, preparation should be distributed & carried at the edge to keep expenses associated with high-latency info transfer to a minimum.

XVI. MOBILE PHONE-BASED HUMANOID ROBOTICS USING COMPLEX AI ON SMALL EMBEDDED SYSTEMS

Until the end of these years, excellent mobile mechanical autonomy was significantly hampered by the estimation, power usage, & computational limitations of the available levels of mobile computing. Although small, hand-held robots like the Khepera have been used in connectivity surveying for many years, applications for them are limited due to their onboard operability & expensive units. More casual devices that can be experienced in the usual AI lab will appear like the Pioneer-II, large enough to carry a tablet or full-size computer chassis, but still more expensive & responsive to needs. considerable dem & due to their size. On the other hand, later a long time has brought approximately an insurgency in accessible

computational capacity in implanted frameworks from the point of view of portable mechanical technology. Littler, more capable & less power-hungry processors, cheaper streak memory, & way better battery innovation have combined to permit distant more viable implanted frameworks than were previous

Our intrigue in humanoid robots is in creating the sorts of wide versatile conduct that are fundamental to back benefit robots in long term. These practices include the ability to adapt effectively to uneven surfaces (such as navigating between grass & rocks), the ability to arrange complex movements such as sliding, carrying, & climbing, & combinations thereof (such as bed picking up dirty clothes below). , & connected to other robots or humans (e.g. moving furniture together). The ubiquitous nature of these tasks poses significant challenges for AI, not to mention intelligent frameworks that run on small embedded processors like mobile phones.

Humanoid robots: Hardware & Software In the physical phase, we start with a humanoid robot pack with mechanical autonomy. This gives them 18 degrees of flexibility, which they can summon, so they employ moderately strong & powerful engines, & are much easier to procure & collect than skeletal components. Scratch & build. The package includes his small AVR ATmega128 controller to monitor the robot's service. In our work, this is used to control the low-level position of the servo motor, so it is often used. Figure 8 8 shows STORM, one of its robots using this stage, next to a Nokia 5500 mobile phone mounted to detect the onboard computer. The main disadvantage of using cell phones is that they provide very few input/output resources. In this way, we integrate a custom IrDA interface based on the Microchip MCP 2150 IrDA handheld into the humanoid device. This allows advanced control of the robot's movements from your mobile phone.

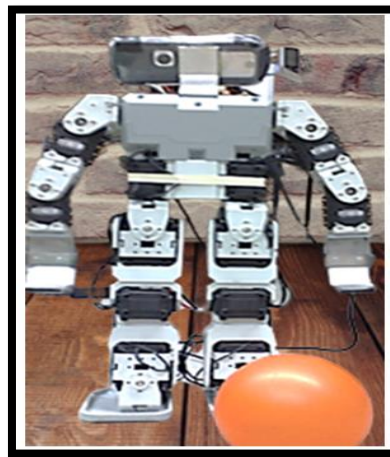

Figure 9: Modified Robotis Bioloid Robot

The Bioloid package comes with firmware that can record & play back basic movements, but it may not be suitable for the complex movements required & the existing firmware should be replaced with our own. The software also supports a 3-axis accelerometer from Analog Gadget, so even phones without an internal accelerometer can use external sensor for dynamic balancing.

Adapting mobile phones for embedded control systems: There are hundreds of cell phones to advertise, & dozens of cell phones that come to the market each year. They are produced in very large quantities, so the price is very competitive with many types of implants. Liszt will find economies of scale & the ability to integrate many critical sensors into a single chassis very appealing. In fact, individual phones from the same manufacturer can use different versions of the same operating system, support different extensions, & even run completely different operating systems. Together Trying to separate the operating system a device is running on from the model number often causes more confusion than it solves. For example, the Nokia 3300 & 3500 are non-programmable Nokia Sort 30 devices, while the Nokia 6600 & 6680 are Nokia Sort 60 devices, making them excellent operating systems for engineering applications. Mechanical engineering It is also important to underst&that mobile phone manufacturers consider these devices to be complete consumables & not "illegal piracy to be used as embedded control frameworks". At best, some companies encourage the development of third-party applications, but these programs often operate in sandboxes that severely limit the hardware the program can use. Cell phones show that they are downplaying these barriers by offering one or two levels of upgrades for high speed, LCD, buttons, remote control, Bluetooth, infrared, & camera very cheaply. . This section describes the tricky aspects of our experience in modifying these devices for robotics applications. This includes working with real-time work frameworks, writing programs, & ultimately developing IrDA interfaces that provide inputs & outputs.

XVII. EMBEDDED AI-BASED DIGI-HEALTHCARE

The advancement of AI has moreover contributed greatly to classifying & foreseeing the well-being status of patients based on their physiological parameters. These parameters may be extricated through diverse sensors that degree organic signals. Besides, computational insights on well-being info empower us to predict & foresee the plausibility of heart infections. The IoT has assisted in revolutionising the IT division & has had a coordinated impact on the therapeutic division. It has permitted analysts to create portable well-being checking gadgets that record crucial well-being parameters on a designed premise. Such frameworks permit therapeutic suppliers to remotely screen their patients & manage their treatment. The IoT innovation has killed geological separations & imperatives between specialists & patients.

It has moreover permitted the provision of state-of-art therapeutic administrations to patients who are found in farther zones & are by & large denied of such extravagances.

AI & IoT have taken the healthcare industry by storm, giving state-of-the-art care indeed to individuals found in far-flung regions. ML strategies are revolutionizing the advanced healthcare division. AI plays an imperative part in IoT-based inaccessible persistent checking frameworks for infection conclusion & anticipation. To preserve the well-being of cardiovascular patients, it is of most extreme significance that their infections are analyzed as soon as conceivable. Besides, within the IoT environment, huge sums of info are created by sensors. This info has important healthcare data & thus it is critical to analyze it for change in restorative innovations. In this respect, AI & ML innovation would be greatly valuable for performing info analytics, classification, & anticipating healthcare conditions based on info & IoT have taken the healthcare industry by storm, giving state-of-the-art care indeed to individuals found in far-flung regions. ML strategies are revolutionizing the advanced

healthcare division. AI plays an imperative part in IoT-based inaccessible persistent checking frameworks for infection conclusion & anticipation. Besides, within the IoT environment, huge sums of info are created by sensors. This info has important healthcare data & thus it is critical to analyze it for change in restorative innovations. In this respect, AI & ML innovation would be greatly valuable for performing info analytics, classification, & anticipating healthcare conditions based on info

Proposed Methodology for AI-Based Digi- Healthcare

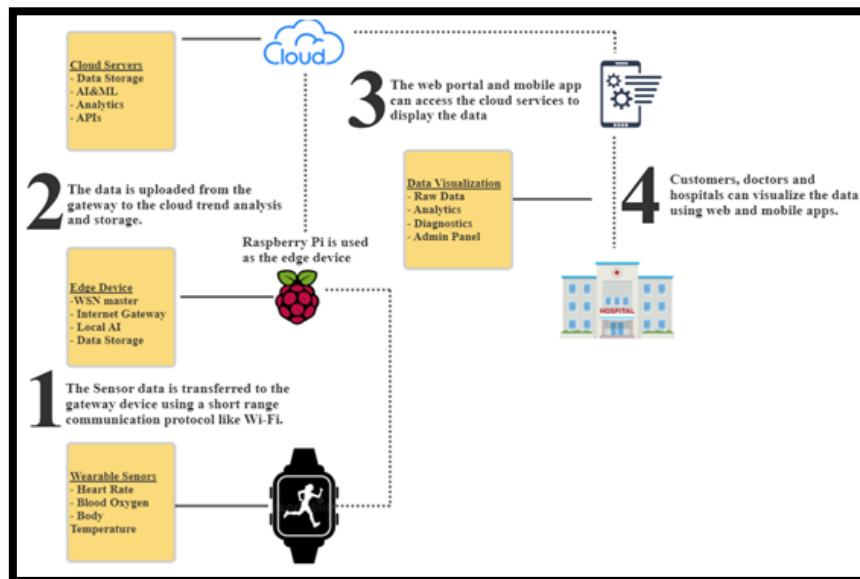

Figure 10: Architecture of System Described

The proposed arrangement is based on the IoMT & AI. The IoT portion is concerned with creating the remote sensor organisation of therapeutic gadgets & sending the info through the web to the cloud. The standard sensors will be utilized to screen the body vitals, & these sensors will send info to the edge where edge computing will be performed to form choices locally utilizing ML induction.

In expansion to this, the vital info & the ML expectation will too be transferred to the cloud for chronicled purposes. The proposed framework would be valuable for the patients, caregivers, & clinics to oversee non-COVID patients at domestic. Specialists can send the patients' restorative counsel remotely but to those who are basic, require real-time observation, require uncommon care, & specialized restorative hardware. Encourage, numerous non-COVID patients are hesitant to visit healing centres owing to the chances of catching this infection due to numerous widespread cases within the hospitals.

The edge hub will incorporate a neighbourhood handling unit for simple to digital change, pre-processing strategies, & info conglomeration in neighbourhood info capacity. It'll furthermore run nearby decision-making based on ML & in case it identifies any variation from the norm within the patient's vitals it'll inform the persistent, the caregivers, & the specialist. Subsequently, the caution will be activated from the edge gadget. The edge hub will exchange pre-processed info to the cloud's database, where the heavier assignments

would be executed such as preparing ML calculations since it has the greatest computation capacity. After preparation, the show is downloaded by the edge gadget utilizing Amazon Web Administrations (AWS) where it can begin forecasting real-time info. This engineering was outlined

Figure 12: Dataset Obtained by AWS

Step 1: Data acquisition: The primary step was to obtain pertinent imperative info to prepare the ML show for the cardiovascular infection forecast. After numerous studies of the datasets accessible online. It contains de-identified info of over 40,000 ICU patients & incorporates broad data on approximately their remaining counting reading of vital signs. The database is additionally facilitated on the AWS cloud.

Step 2: Data pre-processing: This portion of the usage was advance partitioned into steps to guarantee a clean dataset prepared for ML preparation. These steps are encouraged & portrayed below:

- 1. Local instance creation:** SQL dialect is utilized to inquire about social databases for extricating significant data. AWS gives its inquiry benefit known as Athena which is additionally based on standard SQL. As the database was as of now facilitated on the AWS cloud, Athena was utilized to inquire about the database & make a local occurrence of the desired dataset. The adjacent dataset had the necessary data on the three

physiological parameters, namely blood oxygen saturation, body temperature, & heart rate (BPM) (SpO₂). From the Athena support, the dataset was downloaded as a comma-separated (.csv) record.

2. **Data cleaning:** The neighbourhood dataset was at that point assisted prepared & cleaned so that it would be prepared to bolster the preparation of an ML show. It was made beyond any doubt that there were no invalid values in any push & the exactness of the info focus was uniform all through. This step was accomplished utilizing python's info investigation library, pandas. Info cleaning was a critical degree since invalid values & non-uniform info focuses unfavourably influence the exactness of any ML calculation.
3. **Data labelling:** The issue of creating a module for healthcare forecast was demonstrated as a parallel one. Beneath this double show, the anticipated values fell beneath two classes to be specific 'Healthy' & 'Un-healthy', based on the three crucial parameters. The MIMIC-III database had no info which may be consistently utilized as the target lesson for the ML demonstration. Thus, the dataset had to be named consequently so that it can be utilized for preparation purposes. For info naming, the effective numeric computing environment MATLAB was utilized. The info was named concurring to the restoratively acknowledged ordinary human body ranges of crucial parameters which can be found on diverse websites & academic articles. A patient's vitals were named 'Unhealthy' in case they fell out of the run of the ordinary body work.

The ranges are specified henceforth:

- **Body temperature:** 36.5 °C to 37.3 °C
- **Heart rate:** 60 to 100 beats per minute
- **Blood oxygen saturation:** 95% or higher

After naming, the dataset was within the required organize with de-identified time-stamps as seen in Figure 5 where a '0' name indicated 'Healthy' whereas '1' indicated 'Un-healthy'.

4. **Data splitting:** Datasets are often randomly divided into preparation & test sets to use machine learning computations. Although the info is arbitrarily assigned to any of the two groups, it agrees with a particular percentage. The commonly accepted train-test part ratio is 80:20, where the training set comprises 80% of the info & the test set 20%. This section's purpose is to evaluate the ML show & verify its accuracy when compared to the test set. The demonstration is created entirely from training materials, & once it is finished, it is tested on a test set to see whether it is legitimate. For this reason, we use Python to randomly divide the dataset into preparation & test sets that are split 80:20.

Step 3: Applying data models: The well-being status forecast module utilizes machine learning calculations. An add-up to 9 diverse calculations was tried to discover the show that works best. As this was a parallel classification issue, a few conventional calculations were attempted to begin with, at that point the examination moved to much more effective classifiers. At last, a comparative investigation of these calculations is performed to choose the leading show for arrangement at the edge

Step 4: Model selection: After performing a nitty gritty comparative examination, the comes about which are talked about within the following area, the ML show was finalized which would be deployed at the edge. The ultimate demonstration was an optimized K-Nearest Neighbours calculation with an accuracy of 96.26%. The comparative examination is examined within the next segment.

Step 5: Model deployment: After performing a detailed gritty comparative examination, the comes about which is talked about within the following area, the ML show was finalized which would be deployed at the edge. The ultimate demonstration was an optimized K-Nearest Neighbours calculation with accuracy of 96.26%. The comparative examination is examined within the next segment

XVIII. CONCLUSION

The organising, dimensioning, & transmitting of a communication arrangement during the first life stage marks the start of the communication arrangement's life cycle. In this case, the organised administrator emphasises the optimization of speculation & the sparing use of money while addressing the plan's requirements, notably the standard of benefit delivered to or tested by the end-users. Consistent management & control inside the current stage of organised life should assure a progression of the benefit in a specific quality & constant quality the administrations. To stay up with changes in the working environment, network gear & software must be updated as part of the expansion process to enable the administration to maintain benefit quality. Such changes may take the form of a steady increase in the number of supporters, a hazy perception of underused services with a high demand for capacity, etc. The ITU-T specifies the various intelligence columns necessary within the organised insights scenario & explains how to coordinate to a particular level of AI inside the aforementioned workflow forms. In this way, the workflow insights need various large info sets, exactly as the request mapping, which necessitates a continuous gathering of large info volume for the optimization tasks over the whole network life cycle. Additionally, the implementation of such AI decisions & outputs calls for cleverly designed sub-systems that can comprehend & absorb the vast amounts of info that have been gathered & processed.

Adopting AI in cybersecurity can increase user experience, locate problematic devices physically, identify & react to infected devices fast. By providing full network awareness & enabling policy enforcement at each point of connection throughout the network, risk profiling aids IT teams in protecting their infrastructure. Security technologies routinely examine the context of each user's activities as well as the connections & apps present in an environment to determine if they are safe for use or may be abnormal. Embedded AI refers to the use of machine & deep learning to software at the hardware level. Industrial equipment, consumer electronics, agricultural & processing equipment, medical gadgets, cameras, digital watches, household appliances, vending machines, toys, & mobile devices all have embedded systems. The 5G growth architecture was significantly improved with the addition of an AI/ML-driven component. Future research may focus on the design of the Flask server, which promotes communication between the Arbitrator & the model within the 5Gr-VS. The resulting dataset could serve as the input for a subsequent iteration of the operation using a different machine learning model. It is anticipated that wireless network development will continue into the fifth generation & beyond. Industrial equipment, consumer electronics, agricultural & processing equipment, medical gadgets, cameras, digital watches, household

appliances, vending machines, toys, & mobile devices all have embedded systems. The 5G growth architecture was significantly improved with the addition of an AI/ML-driven component. Future research may focus on the design of the Flask server, which promotes communication between the Arbitrator & the model within the 5Gr-VS. The resulting dataset could serve as the input for a subsequent iteration of the operation using a different machine learning model. It is anticipated that wireless network development will continue into the fifth generation & beyond.

Short forms use the in the complete paper

1. AI- Artificial Intelligence
2. ML- Machine Learning
3. IT- Info Technology
4. MR- MATERIAL REVIEW
5. DL- DEEP LEARNING
6. 3GPP-Third Generation Partnership Project
7. LTE-Long Term Evolution
8. 4G-fourth-generation wireless
9. 5G-Fifth-generation wireless
10. B5G- BEYOND 5G
11. LLC- low-latency communications
12. eMTC- enhanced Machine Type Communication
13. 6th Gen- sixth-generation wireless
14. EMD-Enhanced mobile broadband
15. MTC- Massive machine-type communications
16. URLLC- Ultra-reliable low-latency communications
17. V2V- vehicle-to-vehicle
18. MEC- Manufacturing Engineering Centre
19. APIs- Application Programming Interfaces
20. SLAs- Service Level Agreements
21. 5Gr-VS -Vertical Slicer
22. 5GT-SO -Service Orchestrator
23. 5Gr-RL- Resource Layer
24. NFVO-NSO- Network Functions Virtualization Orchestrator- Network Service Orchestrator
25. VNFM-Virtual Network Function Managers
26. NFVO-RO- Network Functions Virtualization Orchestrator -Receiver Output
27. 5GT-SO- Service Object
28. 5GT-MTP- Manufacturing Technical Procedure
29. SLA- Service-level agreement
30. SQL- Structured Query Language
31. LPA-Local Placement Algorithm
32. 3GPP- 3rd Generation Partnership Project
33. 5Gr-VoMS- Virtual Organization Membership Service
34. 5G-IMPS- Immediate Payment Service
35. CST - Computer Science Technology
36. SVM- Support vector machine
37. RBF- radial basis function

38. IQR- The Interquartile Range
39. CV- curriculum vitae
40. CPU- Central Processing Unit.
41. XR- Extended reality
42. BCI- brain-computer interface
43. CRAS- Cost Reduction Alternative Study
44. SDN- Software-defined networking
45. SIM- Subscriber Identity Module
46. IoT- Internet of Things
47. IoE- Institute of Engineering
48. D2D- Diploma to Degree
49. RAN- Radio Access Network
50. UPMS- Ultimate Pandora Memory Stick
51. CPMS- critical path methods
52. ZSM- Zonal Sales Manager
53. ECC- Engineering Critical Component
54. DT- decision tree
55. DNN- deep neural network
56. NB- Nominal Bore
57. RF- Radio-frequency
58. UAV- Unmanned Aerial Vehicle
59. DRL- Differential Reinforcement of Low Rate
60. CNN- convolutional neural network
61. GN- Guidance Note
62. RBM- Restricted Boltzmann Machine
63. AITIA- AI Techniques for Embedded Industrial Applications
64. QoS- Quality of service
65. Network Invasion Detection- NIDs
66. INS- Interface Data Sheet
67. HIDS- Host-based intrusion detection systems
68. ECG- Electrocardiogram
69. ADAS- Advanced Driver Assistance Systems.
70. AVR- automatic voltage regulator
71. MCP- Multi-Chip Package
72. IrDA- Insurance Regulatory & Development Authority
73. LCD- Liquid Crystal Display
74. OS- operating system
75. IoT- Internet of Things
76. IOTM- Internet of Medical Things
77. Wi-Fi- Wireless Fidelity.
78. AWS- Amazon Web Services
79. ICU- Integrated Control Unit
80. BPM- Business process management
81. MIMIC-III- Medical Info Mart for Intensive Care
82. MATLAB- Matrix Laboratory
83. GUI- Graphic User Interface
84. CRAS- Connected Robotics & Autonomous Systems
85. BCI- Brain-Computer interactions

86. XR- Extended reality
87. SDN- Software-Defined Networking
88. NFV- Network Function Virtualization
89. MEC- Multi-access Edge Computing
90. IoE- Internet of Everything
91. D2D- Device-to-Device
92. UPMS- User Plane Micro Services
93. CPMS- Control Plane Micro Service
94. ZSM-Zero-touch network &Service Management
95. ECC- Elliptic Curve Cryptography
96. CAPEX -Capital expenditure
97. operating expenses (OPEX)
98. EU- Engineering Unit
99. AITIA- Aspirin In Transient Ischemic Attacks
100. GPS- Global Positioning System
101. RTS- Real-time scheduling
102. NTMA- Network Traffic Monitoring &Analysis
103. KNN- k-nearest neighbours
104. NGMN- Next Generation Mobile Networks1

CITES AND REFERENCES

- [1] In this paper, the Author describes how Network function virtualization (NFV) has drawn significant attention from both industry & academia. NFV has the potential to lead to significant reductions in operating expenses (OPEX) & capital expenses (CAPEX). We survey the state-of-the-art NFV & identify promising research directions in this area.
- [2] In this paper, the Author describes further details of Network Slicing including the Network slicing concept & definitions.
- [3] In this paper, the Author gives a detailed review regarding the 5G technology, its working pros & cons on the environment.
- [4] 5G networks will pose complex network management challenges. The service orchestration functionality is fundamental to enable fulfilling the requirements of the different verticals. This paper subtle elements of the 5G- Transformer benefit orchestrator execution & operation. It too assesses & profiles benefit creation time appearing how the computerization advertised by the stage permits lessening it from hours to minutes.
- [5] The EU 5 Development extend plans & creates a 5G End-to-End benefit stage. It coordinates AI & ML methods for any decision-making handle. AI/ML-related benefits dealing with operations are well underneath instantiation/termination methods. Online classification can be performed within the arrangement of hundreds of milliseconds.
- [6] The author discusses the potential of embedded machine learning is still not understood well by the majority of the industrial players & Small & Medium Enterprises. This paper presents the approach of the AITIA project, which aims at developing & demonstrating best practices for embedded AI.
- [7] The creator examines, concerning the improvement of real-world humanoid mechanical autonomy applications has been hampered by a need for accessible versatile computational control. Within the final few a long time, a noteworthy number of choices for implanted preparing reasonable for humanoid robots have shown up. Modern devices now supply much in the way of sensor technology that is also potentially of use to roboticists (e.g. accelerometers, cameras, GPS). In this paper, we explore the use of modern mobile phones as a vehicle for the sophisticated AI necessary for autonomous humanoid robots. The author discusses with the rise of the IoT, there has been a growing demand for people counting & occupancy estimation in

Intelligent buildings. This can have a significant impact on energy consumption on a global scale. We present an embedded algorithm for room occupancy estimation based on a thermal sensor with accuracy over the state-of-the-art.

- [8] The author discusses how Artificial Intelligence is becoming more attractive to resolving non-trivial problems including the well-known real-time scheduling (RTS) problem for Embedded Systems. RTS is considered a hard multi-objective optimization problem because it must optimize at the same time three key conflictual objectives.
- [9] The authors discuss the Internet of Medical Things (IoMT) -based remote patient monitoring system which is based on Artificial Intelligence (AI) & edge computing. The system will continuously monitor physiological parameters like body temperature, heart rate, & blood oxygen saturation, & then report the health status to the authenticated users.
- [10] For human intellect, the majority of AI systems are fundamentally complex & unpredictable. In reality, the economic viability of AI-based solutions is hampered by a lack of interpretability. To make AI models more comprehensible, controllable, & reliable, researchers are investigating explainable AI (XAI) methodologies.
- [11] Instead of uploading the whole training set of data, collaborative learning enables participants to train a global model using a subset of parameter changes. Only when the parties involved can be trusted can this privacy-preserving strategy successfully allow privacy protection. In this paper, we present Sec CL, a blockchain-based trusted message board that supports secure collaborative learning.
- [12] Network management relies heavily on Network Traffic Monitoring & Analysis (NTMA). Large-scale networks like the Internet can operate properly because of NTMA. To fully grasp the potential of big data in NTMA, this survey combines NTMA with big data.
- [13] Applications for Machine Learning (ML) to address issues have increased at an unprecedented rate. This study examines the use of several ML approaches in many important networking domains. It also outlines the constraints & provides insights, research difficulties, & potential future directions for ML advancement in networking.
- [14] As networks get increasingly complicated, traditional rule-based congestion control methods tend to lose efficiency & effectiveness. In light of machine learning's enormous success, researchers have started to focus more on machine learning-based systems for end-to-end congestion control.
- [15] 5G wireless communication networks are currently being deployed, & B5G networks are expected to be developed over the next decade. This article studies how AI & machine learning can be leveraged for the design & operation of these networks. The study touches on different aspects of wireless network design & optimization, including channel measurements, modelling, estimation, & estimation.
- [16] In the following Author says that We can deploy a teaching platform on the network platform to guide the teaching of English, which has become one of the teaching methods in many schools. We have changed the traditional teaching mode through the way of human-computer interaction, using people's body movements & gesture info to interact. We also use AI technology to obtain the feature value of the vector angle through the three-dimensional characteristics of people's bones & propose a KNN rapid recognition method.
- [17] Author discusses the potential of embedded machine learning, where intelligent algorithms run in resource-constrained devices rather than in the cloud, which is still not understood well by the majority of the industrial players & Small & Medium Enterprises (SMEs). This paper presents the approach of the AITIA project, a consortium of four Universities which aims at developing & demonstrating best practices for embedded AI.
- [18] In this paper Author talks about a comprehensive survey of the application of AI methods for moving forward the execution of optical communication frameworks & systems. The utilisation of AI-based procedures is, to begin with, a consideration of applications related to optical transmission, extending from execution observation, relief of nonlinearities, & quality of transmission estimation. It moreover presents a rundown of openings & challenges in optical organizing where AI is anticipated to play a key part in no time.

- [19] Author discusses that artificial intelligence techniques have been increasingly adopted to tackle networking problems. Although AI algorithms can deliver high-quality solutions, most are inherently intricate & erratic for human cognition. The need for interpretability colossally prevents the commercial victory of AI-based arrangements in the hone. To manage this challenge, analysts are beginning to investigate explainable AI (XAI) strategies to form AI models interpretable, sensible, & dependable.
- [20] Author discusses one of the recent trends of the Internet of Things (IoT) is that the IoT data are manipulated by Artificial Intelligence (AI) techniques for smart applications. By including AI in existing IoT application programs, a significant coding effort is required. This paper proposes a solution called AI to talk to resolve this issue. It treats the machine learning mechanism as a cyber IoT device.
- [21] Author discusses how the Internet of things has to protect user privacy & address attacks such as spoofing attacks, denial of service (DoS) attacks, jamming, & eavesdropping. We investigate the attack model for IoT systems & review the IoT security solutions based on machine learning (ML) techniques. ML-based IoT authentication, access control, secure offloading, & malware detection schemes to protect data privacy are the focus of this article.
- [22] Here Author discusses that Many computer algorithms have been developed for detecting community structure in networks, but they are computationally demanding & limited to small networks. Here we describe an algorithm that gives excellent results when tested on both computer-generated & real-world networks & is much faster than previous algorithms. We give several example applications, including one to a collaboration network of more than 50 000 physicists
- [23] Here Author discusses that the rise & development of the Internet of Things (IoT) have given birth to the frontier technology of the agricultural IoT, which marks the future trend in agriculture & the IoT. The agricultural IoT can be combined with Zigbee, short-range wireless network technology for monitoring systems
- [24] Here Authors discuss the use of edge Machine Learning for AI-Enabled IoT Devices & provide the info that the world will be populated by billions of connected devices that will be associated with the encompassing environment. Numerous of these gadgets will be based on machine learning models to interpret the meaning & conduct behind sensors' info. The bottleneck will be the tall level of associated things that seem stuff the arrange.
- [25] The author examines the part of Manufactured Insights (AI) that is gigantic within the imagined 6th Gen worldview. Be that as it may, the union between 6th Gen & AI may too be a double-edged sword in numerous cases. This article presents how AI can be utilized in 6th Gen security, conceivable challenges & arrangements.
